METHOD AND APPARATUS FOR JUMP DELAY SLOT CONTROL IN A PIPELINED PROCESSOR

5 This application claims priority to U.S. Provisional Patent Application Serial No. 60/134,253 filed May 13, 1999, entitled "Method And Apparatus For Synthesizing And Implementing Integrated Circuit Designs," and to co-pending U.S. Patent Application No. 09/418,663 filed October 14, 1999, entitled "Method And Apparatus For Managing The Configuration And Functionality Of A Semiconductor Design," which claims priority to U.S. Provisional Patent Application Serial No. 60/104,271 filed October 14, 1998, of the

10 same title.

Background of the Invention

1. Field of the Invention

15 The present invention relates to the field of integrated circuit design, specifically to the use of a hardware description language (HDL) for implementing instructions in a pipelined central processing unit (CPU) or user-customizable microprocessor.

2. Description of Related Technology

20 RISC (or reduced instruction set computer) processors are well known in the computing arts. RISC processors generally have the fundamental characteristic of utilizing a substantially reduced instruction set as compared to non-RISC (commonly known as "CISC") processors. Typically, RISC processor machine instructions are not all micro-coded, but rather may be executed immediately without decoding, thereby affording significant economies in terms of processing speed. This "streamlined" instruction handling capability furthermore allows greater simplicity in the design of the processor (as

0052387/031300

compared to non-RISC devices), thereby allowing smaller silicon and reduced cost of fabrication.

RISC processors are also typically characterized by (i) load/store memory architecture (i.e., only the load and store instructions have access to memory; other instructions operate via internal registers within the processor); (ii) unity of processor and compiler; and (iii) pipelining.

Pipelining is a technique for increasing the performance of processor by dividing the sequence of operations within the processor into segments which are effectively executed in parallel when possible. In the typical pipelined processor, the arithmetic units associated with processor arithmetic operations (such as ADD, MULTIPLY, DIVIDE, etc.) are usually "segmented", so that a specific portion of the operation is performed in a given segment of the unit during any clock cycle. Fig. 1 illustrates a typical processor architecture having such segmented arithmetic units. Hence, these units can operate on the results of a different calculation at any given clock cycle. As an example, in the first clock cycle two numbers A and B are fed to the multiplier unit 10 and partially processed by the first segment 12 of the unit. In the second clock cycle, the partial results from multiplying A and B are passed to the second segment 14 while the first segment 12 receives two new numbers (say C and D) to start processing. The net result is that after an initial startup period, one multiplication operation is performed by the arithmetic unit 10 every clock cycle.

The depth of the pipeline may vary from one architecture to another. In the present context, the term "depth" refers to the number of discrete stages present in the pipeline. In general, a pipeline with more stages executes programs faster but may be more difficult to program if the pipeline effects are visible to the programmer. Most pipelined processors are either three stage (instruction fetch, decode, and execute) or four stages (such as instruction fetch, decode, operand fetch, and execute, or alternatively instruction fetch, decode/operand fetch, execute, and writeback), although more or less stages may be used.

Interlocks are necessary with pipelined architectures generally to address, inter alia, the case where a following instruction (n+1) in an earlier pipeline stage needs the result of the instruction n from a later stage. A simple solution to the aforementioned problem is to

delay the operand calculation in the instruction decoding phase by one or more clock cycles. "Scoreboarding" may be used, wherein a bit is attached to each processor register to act as an indicator of the register content. Alternatively, NOPs (no-operation opcodes) may be inserted in the code so as to delay the appropriate pipeline stage when desired.

- 5 This later approach has been referred to as "software interlocking" and has the disadvantage of increasing the code size and complexity of programs that employ instructions that require interlocking.

Another important consideration in processor design is program branching or "jumps". All processors support some type of branching instructions. Simply stated,
10 branching refers to the condition where program flow is interrupted or altered. Other operations such as loop setup and subroutine call instructions also interrupt or alter program flow in a similar fashion. The term "jump delay slot" is often used to refer to the slot within a pipeline subsequent to a branching or jump instruction being decoded. Branching may be conditional (i.e., based on the truth or value of one or more parameters)
15 or unconditional. It may also be absolute (e.g., based on an absolute memory address), or relative (e.g., based on relative addresses and independent of any particular memory address).

Branching can have a profound effect on pipelined systems. By the time a branch instruction is inserted and decoded by the processor's instruction decode stage (indicating
20 that the processor must begin executing a different address), the next instruction word in the instruction sequence has been fetched and inserted into the pipeline. One solution to this problem is to purge the fetched instruction word and halt or stall further fetch operations until the branch instruction has been executed, as illustrated in Fig. 2. This approach, however, by necessity results in the execution of the branch instruction in
25 several instruction cycles, this number typically being between one and the depth of the pipeline employed in the processor design. This result is deleterious to processor speed and efficiency, since other operations can not be conducted by the processor during this period.

Alternatively, a delayed branch approach may be employed. In this approach, the pipeline is not purged when a branch instruction reaches the decode stage, but rather
30 subsequent instructions present in the earlier stages of the pipeline are executed normally

before the branch is executed. Hence, the branch appears to be delayed by the number of instruction cycles necessary to execute all subsequent instructions in the pipeline at the time the branch instruction is decoded. This approach increases the efficiency of the pipeline as compared to multi-cycle branching described above, yet also complexity (and ease of understanding by the programmer) of the underlying code.

Based on the foregoing, processor designers and programmers must carefully weigh the tradeoffs associated with utilizing either the delayed or multi-cycle branching approaches of the prior art. What is needed is an improved approach to branching/jumping which overcomes or mitigates these tradeoffs while providing the additional flexibility.

Furthermore, as more pipeline stages (and even multiple multi-stage pipelines) are added to processor designs, the benefits of improved and simplified branching and instruction execution within the processor increased manifold. Additionally, the ability to readily synthesize such improved pipelined processor designs in an application-specific manner, and using available synthesis tools, is of significant utility to the designer and programmer.

Summary of the Invention

The present invention satisfies the aforementioned needs by providing an improved method and apparatus for executing instructions within a digital processor architecture.

In a first aspect of the invention, an improved method of managing branching and instruction execution within a pipelined processor is disclosed. In one exemplary embodiment, three discrete delay slot modes are implemented using predetermined bits of the instruction word. These three modes include: (i) execution of a delay slot instruction under all circumstances; (ii) the execution of a delay slot instruction only if a jump is taken, and (iii) a pipeline stall or bubble in place of an instruction execution if a jump is taken. A pipeline bubble is analogous to a NOP no-operation instruction in that it is an instruction which flows through the pipeline without performing any operation. It will typically be an instruction which has been 'killed' after having been fetched into the pipeline. The availability of these three modes provides the programmer with additional flexibility in jump delay slot control using existing branch or similar instructions.

Unconstrained and constrained exemplary synthesized logic implementing the aforementioned delay slot method is also disclosed.

In a second aspect of the invention, an improved method of synthesizing the design of an integrated circuit incorporating the aforementioned jump delay slot method is disclosed. In one exemplary embodiment, the method comprises obtaining user input regarding the design configuration; creating customized HDL functional blocks based on the user's input and existing library of functions; determining the design hierarchy based on the user's input and the library and generating a hierarchy file, new library file, and makefile; running the makefile to create the structural HDL and scripts; running the generated scripts to create a makefile for the simulator and a synthesis script; and synthesizing the design based on the generated design and synthesis script.

In a third aspect of the invention, an improved computer program useful for synthesizing processor designs and embodying the aforementioned method is disclosed. In one exemplary embodiment, the computer program comprises an object code representation stored on the magnetic storage device of a microcomputer, and adapted to run on the central processing unit thereof. The computer program further comprises an interactive, menu-driven graphical user interface (GUI), thereby facilitating ease of use.

In a fourth aspect of the invention, an improved apparatus for running the aforementioned computer program used for synthesizing logic associated with pipelined processors is disclosed. In one exemplary embodiment, the system comprises a stand-alone microcomputer system having a display, central processing unit, data storage device(s), and input device.

In a fifth aspect of the invention, an improved processor architecture utilizing the foregoing jump delay slot methodology and constrained/unconstrained synthesized logic is disclosed. In one exemplary embodiment, the processor comprises a reduced instruction set computer (RISC) having a three stage pipeline comprising instruction fetch, decode, and execute stages which are controlled in part by the aforementioned jump delay slot methodology.

30

Detailed Description of the Invention

25 Reference is now made to the drawings wherein like numerals refer to like parts throughout.

As used herein, the term "processor" is meant to include any integrated circuit or other electronic device capable of performing an operation on at least one instruction word including, without limitation, reduced instruction set core (RISC) processors such as the
30 ARC user-configurable core manufactured by the Assignee hereof, central processing units

(CPUs), and digital signal processors (DSPs). The hardware of such devices may be integrated onto a single piece of silicon ("die"), or distributed among two or more die. Furthermore, various functional aspects of the processor may be implemented solely as software or firmware associated with the processor.

5 Additionally, it will be recognized by those of ordinary skill in the art that the term "stage" as used herein refers to various successive stages within a pipelined processor; i.e., stage 1 refers to the first pipelined stage, stage 2 to the second pipelined stage, and so forth.

 It is also noted that while the following description is cast in terms of VHSIC hardware description language (VHDL), other hardware description languages such as Verilog® may be used to describe various embodiments of the invention with equal
10 success. Furthermore, while an exemplary Synopsys® synthesis engine such as the Design Compiler 1999.05 (DC99) is used to synthesize the various embodiments set forth herein, other synthesis engines such as Buildgates® available from, inter alia, Cadence Design Systems, Inc., may be used. IEEE std. 1076.3-1997, IEEE Standard VHDL
15 Synthesis Packages, describe an industry-accepted language for specifying a Hardware Definition Language-based design and the synthesis capabilities that may be expected to be available to one of ordinary skill in the art.

 Lastly, it will be recognized that while the following description illustrates specific embodiments of logic synthesized by the Assignee hereof using the aforementioned
20 synthesis engine and VHSIC hardware description language, such specific embodiments being constrained in different ways, these embodiments are only exemplary and illustrative of the design process of the present invention. Furthermore, while a 1.0 um process was specified for these embodiments, other fabrication processes (such as 0.35 um or 0.18 um) may conceivably be used in conjunction with the invention disclosed herein.

25

Jump Delay Slot Modes

 The improved method of controlling jump delay slots and their encoding within a processor according to the present invention is now described.

 The present invention generally comprises a plurality of different "jump modes" or
30 modifiers. These modifiers control the operation of the processor during jumping;

specifically, the execution of instructions subsequent to or in an earlier pipeline stage than that of the jump instruction itself. Collectively, these modifiers provide the programmer with benefits not afforded by either the multi-cycle or delayed branch approaches in isolation since the programmer can arrange the program code so that the pipeline operates in the desired fashion during such jump or branching operations.

Referring now to Fig. 3, the generalized method 300 of controlling the execution of instructions during jumping within a pipelined processor according to the present invention is described. First, in step 302, a program adapted to run on the processor and comprising a plurality of instruction "words" is provided. Each instruction word in the program is represented by and comprises a plurality of data bits, and at least one of the instruction words comprises a jump instruction. In the present context, the term 'instruction set' is used to describe the complete set of every possible instruction which could be executed on the processor, and the term 'program' is used to describe a specific sequence of instructions selected from the instruction set of the processor to achieve a specific purpose. As used herein, the term "jump" refers to any branch, jump, loop setup, or call instructions, although other instructions requiring a change in the flow of the instruction processing of the processor may conceivably be used in conjunction with the disclosed invention.

Next, in step 304, one of a plurality of predetermined values is assigned to at least one of the data bits of the jump instruction. In one embodiment, two data bits of the jump instruction word are designated to carry the jump delay slot mode information as described below with reference to Table 1. With the allowable binary states of "0" and "1" for each of the two bits, 2^2 or 4 unique combinations may be formed, each designating a different jump delay slot mode. It will be recognized, however, that any different number of unique (or non-unique) modes may be designated by using more or less data bits, or even a different numerical base employed if desired.

Next, in step 306, the at least one jump instruction containing the jump delay slot mode information is decoded by the processor. Methods and apparatus useful for instruction decoding are well known in the computer arts, and accordingly will not be described further herein. It is noted, however, that in contrast to prior art methods of decoding instructions, decoding of jump instructions within the instruction set of the

present invention includes not only decoding of the instruction itself (step 307), but also decoding and analysis of the designated jump delay slot mode data bits (step 308) as previously described.

5 In step 310, the designated jump delay slot mode is executed, according to the functionality specified by the programmer in step 304.

Fig. 3a illustrates one exemplary embodiment of the method of executing the designated jump delay slot mode per step 310 of Fig. 3. In a first step 312, the data bits designated in step 304 to carry the delay slot mode information are read to determine the jump delay slot mode selected within the instruction being decoded. Next, in step 314, the
10 selected delay slot mode is analyzed to determine if it is conditional (i.e., dependent upon another parameter such as whether or not a jump to another program address is taken). If the selected mode is conditional, the status of the parameter is analyzed in steps 316 and 317 to determine the "truth" thereof. If the condition is true, the required actions for a true condition are executed per step 318. If the condition is not true, the required actions for a
15 false condition are taken (or alternatively no action is taken) per step 320. If the selected mode is not conditional on any parameter, the action required by that mode (such as execution of a subsequent instruction within the pipeline, or a pipeline stall) is executed in step 322.

In one exemplary embodiment of the foregoing method 300, the following three
20 jump modifiers (delay slot modes) are defined:

- (1) **ND** ("No Delayed Instruction Slot") - Only executes the next instruction in pipeline when not jumping; if jumping, one cycle pipeline stall or bubble inserted
- 25 (2) **D** ("Delayed Instruction Slot") - Always execute the next instruction regardless of jump status
- (3) **JD** ("Jump Delayed Instruction Slot") - Only execute the next instruction when jumping; if not jumping, one cycle pipeline stall or bubble inserted

30

The first mode (1) provides a pipeline "stall" of one or more cycles in place of an instruction execution if a jump is taken. The second mode (2) provides for execution of a delay slot instruction (i.e., the instruction present in the slot following the jump instruction after decode under all circumstances. The third mode (3) provides for the execution of a delay slot instruction only if a jump is taken. While the following discussion is cast in terms of these three modes, it will be recognized that not all three modes are required to be used collectively or within the same instruction set, and further that other additional delay modes with different functionality may be added to the instruction set to further enhance programming flexibility and control.

The availability of the foregoing three distinct modes provides the programmer with additional flexibility in jump delay slot control, due in part to the ability to customize the instruction set while not being limited to pure multi-cycle or delayed branching approaches as previously described. Specifically, by inserting the appropriate jump delay mode codes within certain instructions within the program, the programmer may obtain beneficial characteristics of both the multi-cycle and delay branching approaches within one processor and one instruction set.

Table 1 illustrates the jump delay mode coding associated with the aforementioned three delay slot modes. In the illustrated embodiment, two binary data bits of the processor instruction word (IW) are used to indicate each one of the three delay slot modes **ND**, **D**, and **JD**:

Table 1

IW Bits	Syntax	Mode
00	.nd	No Delay slot instruction execution if jump taken - one cycle pipeline stall or bubble instead.
01	.d	Delay slot instruction always executed.
10	.jd	Delay slot instruction executed only if Jump is taken
11		(Reserved)

Table 2 is a truth table derived from the defined jump delay slot modes of Table 1:

Table 2

Jump Delay Slot Mode	Condition Truth	
	Jump Taken	No Jump Taken
.nd	One cycle stall or bubble	Delay slot instruction execution
.d	Delay slot instruction execution	Delay slot instruction execution
.jd	Delay slot instruction execution	No delay slot instruction execution

- 5 The following assembly language code illustrates examples of the syntax and operation of each of the respective jump delay slot modes of Table 1 using a conditional branch instruction (beq) to program location 'target' followed by a mathematical (add) instruction:

- 10 (1) beq.nd target ;
add r1,r1,1 ; "add" not executed if jump taken
- (2) beq.d target ;
add r1,r1,1 ; "add" always executed
- 15 (3) beq.jd target :
add r1,r1,1 ; "add" executed only if jump taken

The fourth mode ("11") of Table 1 may be used for other jump mode or non-jump mode functions as desired, thereby affording the programmer even further flexibility

20 Additionally, while two bits of the instruction word are illustrated in the embodiment of Table 1, it will be appreciated that other numbers and arrangements of bits (including their position within the instruction word and their syntax) may conceivably be used. For example, three non-contiguous bits could be used to represent up to eight separate jump delay slot modes.

25 Table 3 illustrates a second embodiment of the jump delay slot modes of the invention utilizing five jump delay slot modes (four plus one reserved) based on three data bits within the IW:

Table 3

IW Bits	Syntax	Mode
000		(Reserved)
001	.jd	Delay slot instruction executed only if Jump is taken
010	.d	Delay slot instruction always executed.
011	.nd1	No Delay slot instruction execution if jump taken - one cycle pipeline stall instead.
100		(Reserved)
101		(Reserved)
110		(Reserved)
111	.nd2	No Delay slot instruction execution if jump taken - two cycle pipeline stall instead.

In the illustrated embodiment(s), jump instructions present within the instruction set may stop execution of (i.e. "kill") other instruction types, depending on two factors: (i) the selected delay slot mode, and (ii) whether the jump instruction's condition is true. The following four instructions illustrate the foregoing principles in the context of VHDL coding associated with Applicant's ARC RISC processor:

1. Regular jump instruction:

```

ip2rjmp    <= '1' WHEN ip2iv = '1'    AND (ip2i = obcc
                                         OR  ip2i = oblcc
                                         OR  ip2i = ojcc ) ELSE
                                         '0';

```

2. Loop setup instruction:

```

ip21pcc    <= '1' WHEN ip2iv = '1'    AND (ip2i = o1pcc) ELSE
                                         '0';

```

3. Jumping/nojump signals:

```

ip2jumping <= (ip2rjmp AND ip2condtrue) OR (ip21pcc AND NOT ip2condtrue);

```

```

ip2nojump  <= (ip2rjmp AND NOT ip2condtrue) OR (ip21pcc AND ip2condtrue);

```

4. "Kill" signal:

5 ip2killnext<= '1' WHEN ((ip2dd = dmk) AND ip2bch = '1')
 OR ((ip2dd = dmnd) AND ip2jumping = '1')
 OR ((ip2dd = dmjd) AND ip2nojump = '1')
ELSE
 '0';

10 p2killnext <= ip2killnext;

It is noted that the ip2killnext instruction of the illustrated embodiment includes p2iv (pipeline stage 2 instruction valid signal) and a full decode for a jump operation, so that it can be used within the pipeline control logic ("pipectl") without any further decode apart from en2 (pipeline stage 2 enabled/stalled signal). This feature reduces decode delays and permits faster instruction execution. While the decode technique used in this example results in the foregoing operational benefits, it will be recognized that this technique is not essential to the practice of the present invention.

Appendix A illustrates one exemplary embodiment of the VHDL used for synthesis of the foregoing jump delay slot modes of the present invention.

Appendix B provides an exemplary synthesis script for delay slot synthesis using the Synopsys® synthesis engine.

It is also noted that the methods and apparatus of the present invention may be used in conjunction with (either alone or collectively) other methods of pipeline control and interlock including, inter alia, those disclosed in Applicant's co-pending U.S. Patent Application entitled "Method And Apparatus For Jump Control In A Pipelined Processor," as well as those disclosed in Applicant's co-pending U.S. Patent Application entitled "Method And Apparatus For Processor Pipeline Segmentation and Reassembly," both filed contemporaneously herewith, both being incorporated by reference herein in their entirety. Furthermore, various register encoding schemes, such as the "loose" register encoding described in Applicant's co-pending U.S. Patent Application entitled "Method and Appatatus for Loose Register Encoding Within a Pipelined Processor" filed contemporaneously herewith and incorporated by reference in its entirety herein, may be used in conjunction with the jump delay slot invention described herein.

Method of Synthesizing

Referring now to Fig. 4, the method 400 of synthesizing logic incorporating the jump delay slot mode functionality previously discussed is described. The generalized method of synthesizing integrated circuit logic having a user-customized (i.e., "soft") instruction set is disclosed in Applicant's co-pending U.S. Patent Application Serial No. 09/418,663 entitled "Method And Apparatus For Managing The Configuration And Functionality Of A Semiconductor Design" filed October 14, 1999, which is incorporated herein by reference in its entirety.

While the following description is presented in terms of an algorithm or computer program running on a microcomputer or other similar processing device, it can be appreciated that other hardware environments (including minicomputers, workstations, networked computers, "supercomputers", and mainframes) may be used to practice the method. Additionally, one or more portions of the computer program may be embodied in hardware or firmware as opposed to software if desired, such alternate embodiments being well within the skill of the computer artisan.

Initially, user input is obtained regarding the design configuration in the first step 402. Specifically, desired modules or functions for the design are selected by the user, and instructions relating to the design are added, subtracted, or generated as necessary. For example, in signal processing applications, it is often advantageous for CPUs to include a single "multiply and accumulate" (MAC) instruction. In the present invention, the instruction set of the synthesized design is modified so as to incorporate the foregoing jump delay slot modes (or another comparable jump delay slot control architecture) therein. Specifically, in the present embodiment, one of a plurality of predetermined values indicating the designated jump delay slot mode is represented by two data bits of the jump instruction word as described above with reference to Table 1. The technology library location for each VHDL file is also defined by the user in step 402. The technology library files in the present invention store all of the information related to cells necessary for the synthesis process, including for example logical function, input/output timing, and any

associated constraints. In the present invention, each user can define his/her own library name and location(s), thereby adding further flexibility.

Next, in step 403, customized HDL functional blocks based on the user's input and the existing library of functions specified in step 402 are created.

5 In step 404, the design hierarchy is determined based on the user's input and the aforementioned library files. A hierarchy file, new library file, and makefile are subsequently generated based on the design hierarchy. The term "makefile" as used herein refers to the commonly used UNIX makefile function or similar function of a computer system well known to those of skill in the computer programming arts. The makefile
10 function causes other programs or algorithms resident in the computer system to be executed in the specified order. In addition, it further specifies the names or locations of data files and other information necessary to the successful operation of the specified programs. It is noted, however, that the invention disclosed herein may utilize file structures other than the "makefile" type to produce the desired functionality.

15 In one embodiment of the makefile generation process of the present invention, the user is interactively asked via display prompts to input information relating to the desired design such as the type of "build" (e.g., overall device or system configuration), width of the external memory system data bus, different types of extensions, cache type/size, etc. Many other configurations and sources of input information may be used, however,
20 consistent with the invention.

In step 406, the makefile generated in step 404 is run to create the structural HDL. This structural HDL ties the discrete functional block in the design together so as to make a complete design.

Next, in step 408, the script generated in step 406 is run to create a makefile for the
25 simulator. The script to generate a synthesis script is also run in step 408.

At this point in the program, a decision is made whether to synthesize or simulate the design (step 410). If simulation is chosen, the user runs the simulation using the generated design and simulation makefile (and user program) in step 412. Alternatively, if synthesis is chosen, the user runs the synthesis using the synthesis script(s) and generated
30 design in step 414. After completion of the synthesis/simulation scripts, the adequacy of

parallel ports, timers, counters, high current drivers, analog to digital (A/D) converters, digital to analog converters (D/A), interrupt processors, LCD drivers, memories and other similar devices. Further, the processor may also include custom or application specific circuitry. The present invention is not limited to the type, number or complexity of peripherals and other circuitry that may be combined using the method and apparatus. Rather, any limitations are imposed by the physical capacity of the extant semiconductor processes which improve over time. Therefore it is anticipated that the complexity and degree of integration possible employing the present invention will further increase as semiconductor processes improve.

10 It is also noted that many IC designs currently use a microprocessor core and a DSP core. The DSP however, might only be required for a limited number of DSP functions, or for the IC's fast DMA architecture. The invention disclosed herein can support many DSP instruction functions, and its fast local RAM system gives immediate access to data. Appreciable cost savings may be realized by using the methods disclosed
15 herein for both the CPU & DSP functions of the IC.

Additionally, it will be noted that the methodology (and associated computer program) as previously described herein can readily be adapted to newer manufacturing technologies, such as 0.18 or 0.1 micron processes, with a comparatively simple re-synthesis instead of the lengthy and expensive process typically required to adapt such technologies using “hard” macro prior art systems.

Referring now to Fig. 8, one embodiment of a computing device capable of synthesizing, inter alia, the jump delay mode logic structures of Figs. 5 and 6 herein is described. The computing device 800 comprises a motherboard 801 having a central processing unit (CPU) 802, random access memory (RAM) 804, and memory controller 805. A storage device 806 (such as a hard disk drive or CD-ROM), input device 807 (such as a keyboard or mouse), and display device 808 (such as a CRT, plasma, or TFT display), as well as buses necessary to support the operation of the host and peripheral components, are also provided. The aforementioned VHDL descriptions and synthesis engine are stored in the form of an object code representation of a computer program in the RAM 804 and/or storage device 806 for use by the CPU 802 during design synthesis, the latter being
